

## APPENDIX 5A-1

# INTERPRETATION OF SIMULATION OUTPUT

Peng Chau outfall consists of 2 risers, each of 4 jets.

The outfall has been designed to allow adequate distance between the 2 risers and no side merging are encountered. The following categories of plumes are observed in the modeled scenarios for each riser:

- 1) Non merging surfacing plumes
- 2) Non merging trapping plumes
- 3) Merging surfacing plumes
- 4) Merging trapping plumes

For determination of initial dilutions of **categories 1 and 2**, minimum initial dilution at the maximum plume rise-height of 4 simulated jets are adopted as the representative initial dilution for the modeled scenario, as a conservative approach.

For determination of initial dilutions of **categories 3 and 4** where plume merging occur, composite dilution of 4 simulated jets are determined by the following approaches:

### Determination of Composite Dilution

Composite dilutions from merged plumes are determined with the aid of the visual component of VISJET. The composite dilution factor is obtained by cutting a vertical plane at the position defined as the downstream distance or edge of the ZID. This is applied to surfacing plumes and trapped plumes. For surfacing plume, the determination of this downstream distance is straight forward. The downstream distance in the close vicinity to where the minimum dilution at surface layer (centre) level occurs for all jets of the riser are compared and the longest downstream distance is adopted. For trapped plumes, the determination of the maximum downstream distance for a riser is based on the following steps:

- ❑ Define the downstream distance for each jet
  - For the jet in which the downstream distance at maximum rise level is available in the output files, the downstream distance at maximum rise level (depth) is adopted.
  - For the jet in which the downstream distance at maximum rise level (depth) is NOT available in the output files, the downstream distance at trapping level is adopted.
- ❑ Compare the downstream distance for each riser
  - Compare the downstream distances of each jet on the same riser (4 jets per riser) and determine the longest downstream distance.

While the longest downstream distance of all jets in the same riser is used to define the position of the vertical cutting plane, some jets may never reach this plane as their jet momentum reaches zero prior to this defined position. This issue is resolved by simulating these scenarios using the continuous mode option in VISJET, in which the cross sectional area of each evolved effluent plume is projected beyond its classically defined near field extents onto the vertical cutting place.

Once this is completed a composite dilution of the projected jets can be obtained. In the situation when effluent plume jets merge, the value of the composite initial dilution of the merged jets for the vertical cutting plane as defined above, is calculated within VISJET and recorded.

As the configurations of two outfall risers are identical, output files from one riser (4 jets) are provided in **Appendix 5A-2**.
