2. Fixed Box Model

Develop a model to determine COPC concentration in air

To convert COPC concentration levels in soil to air emission, the following fixed-box model has been used and the subsequent assumptions listed out-

$$c = b + \frac{qL}{uH}$$

Where

- c = concentration of pollutant in air, (mg/m³)
- b = background concentration of pollutant, (mg/m³)
- q = emission rate per unit area, (mg/s*m²)
- L = dimension of project side parallel to wind direction, (m)
- u = wind speed, (m/s)
- H = mixing height, (m)

Source: Nevers, N.D. (1995). *Air Pollution Control Engineering*. McGraw-Hill, Inc..

Assumptions:

Fixed-box model calculations based on a consideration of the Subject Site as a rectangular box- with dimensions *W*, *L*, and *H* representing the width, length, and height, respectively.

1. Background concentration. The average of the latest 5 years data (2008-2012) recorded at EPD's Yuen Long air quality monitoring station was taken, and summarized here:

Table 1 Background Concentration

	As	Cd	Pb	Ni	Cr	*Cr(VI)	Mn	Hg
Yuen Long (mg/m ³)	4.66E-06	1.24E-06	4.88E-05	5.34E-06	2.72E-06	3.54E-07	2.00E-05	2.20E-07

*Note: Cr(VI) account for 13% of total Chromium. Source: Lau, A.K.H. et al, (2003) "Assessment of Toxic Air Pollutant Measurements in Hong Kong", pg. 40

Background concentration is taken as zero when calculating for cancer risk, as the approach is to assess the incremental ("excess") lifetime cancer risk as a result of decommissioning works only.

2. Dimension L. The Subject Site is split into two segments: "Site" and "Access

Road”. The length of fixed-box under “wind erosion” scenario is taken as the longest perpendicular side for the Site and Access Road, which are 250m and 500m respectively. The length of fixed-box under “heavy construction” scenario for Site and Access Road is taken as 15m, assumed based on the volume of excavated material handled per day. It is estimated that approximately 15,000m³ (30,000m² in area x 0.5m in depth) of PFA material will be handled over the course of the entire construction period, i.e. 180 working days, which means each day would operate on 83m³ of PFA material. Assuming a depth of 0.5m is operated on each day, the area of excavated material per day is 166m² (12.9m x 12.9m). As conservative approach, the length of the box for active heavy construction will be assumed to be 15m.

Under “mitigated” case, the non-active area (about 50% of the total area) will be covered, and hence the length of the fixed-box is reduced by half under the “wind erosion” scenario only (i.e. 125m and 250m for Site and Access Road respectively); the length of fixed-box for “heavy construction” scenario remains the same for both unmitigated and mitigated.

3. Hourly wind speed at a mixing height of 20m was obtained from EPD’s 2010 MM5 data, under grid (10,36).
4. This turbulence is strong enough in the upwind direction that the pollutant concentration is uniform in the whole volume of air over the assessment area and not higher at the downwind side than the upwind side.
5. No pollutant leaves or enters through the top of the box, nor through the sides that are parallel to the wind direction
6. The air pollutant emission rate per unit area is given by q. The air pollutant pertaining to the site is identified as fugitive dust/PFA emitted as a result of heavy construction activities due to the proposed work and wind erosion. Emission rates are based on USEPA’s Compilation of Air Pollutant Emission Factors 5th edition, 1995 (AP-42).
7. Working schedule provided in Table 2 below.

Table 2 Working Schedule

Section	Access Road	Site	Working hours
Start	Sep-15	Nov-15	07:00 – 19:00
End	Nov-15	Mar-16	

3. Dust Suppression Efficiency

The Removal efficiency is estimated based on Equation 3-2 of USEPA's "Control of Open Fugitive Dust Sources" (EPA-45/3-88-008)

$$C = 100 - (0.8 * p * d * t) / i$$

Where:

- C = average control efficiency, in percent
- p = potential average hourly daytime evaporation rate, in mm/hr
- d = average hourly daytime traffic rate, in vehicles per hour
- t = time between application, in hr
- i = application intensity, in L/m²

According to the records at King's Park between 1981-2010 (http://www.weather.gov.hk/cis/normal/1981_2010/normals_e.htm), the total evaporation recorded in Hong Kong is 1227.3mm.

Therefore,

- p = 0.0049 x 0.03937 x 1227.3 = 0.2368 mm/h
- d = 20 vehicles per hour, as estimated by engineer at an active construction site
- t = 10 times watering per 12 hr working day = 12/10 = 1.2 hr
- i = 0.5 L/m², minimum application intensity, as requirement will be specified in tender document

Therefore, for a water spraying frequency of 10 times per day, the control efficiency is calculated as follows:

$$C = 100 - (0.8 * 0.2368 * 20 * 1.2) / 0.5$$

The estimated dust suppression efficiency is 90.9%.

4. Cancer Risk Calculations

The calculation of inhalation cancer risk is based on the following equation:

$$\text{Cancer Risk} = \text{EC} \times \text{URF}$$

Where:

EC = Exposure concentration ($\mu\text{g}/\text{m}^3$)

URF = Unit risk factor ($\mu\text{g}/\text{m}^3$)⁻¹

The exposure concentration and respective cancer risks have been calculated for each COPC, and detailed in **Table 4** and **5** respectively.

5. Non-Cancer Risk Calculation

For non-carcinogenic COPCs, the potential for non-cancer effects is evaluated by comparing the estimated maximum COPCs in 1-hr average (acute) and long-term average COPCs (total hours during decommissioning period) with the respective air quality guideline value/reference level. Background concentrations are included under wind erosion scenario only. The comparison results are summarised in **Table 6** and **7**.
